

# Fiat micro-vett BMS

Connections and how (i think!) it works in general

Updated 23. July 2017

# Bms nodes

The BMS CAN bus runs at 125 kbps

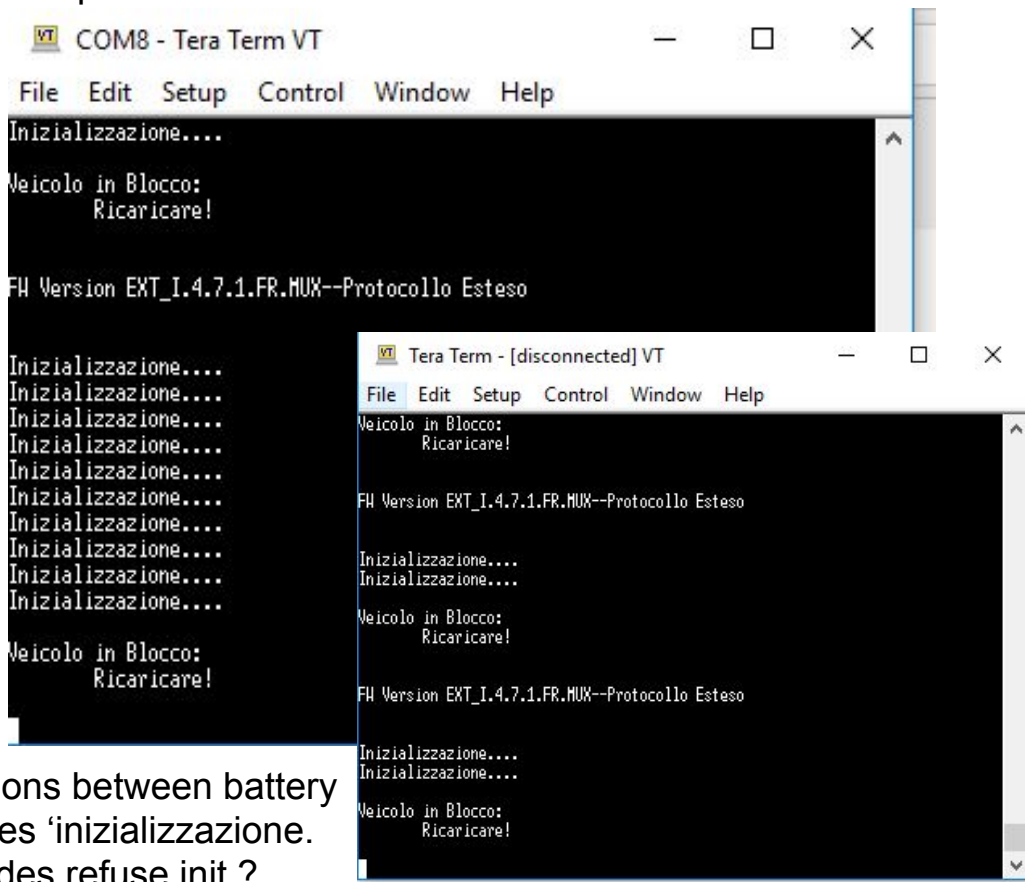

There are 10 nodes on it:

9 x battery packs

1 x ansaldo inverter

1 x ??

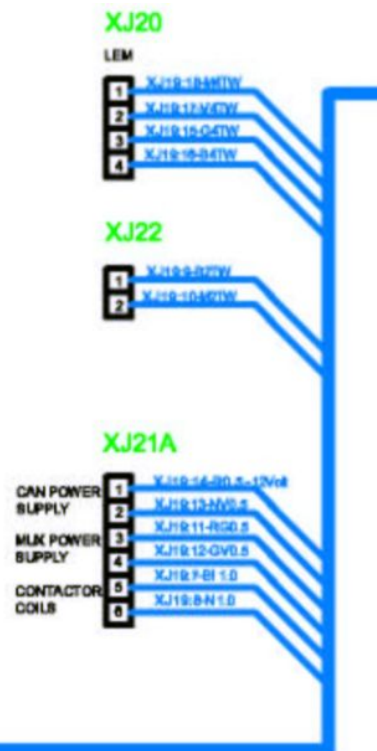

Not sure if this is the CAN nodes, or 10 separate units on the MUX bus ?

After repairing connections between battery packs rear, only two lines 'inizializzazione. Why do the two last nodes refuse init ?

XJ18A

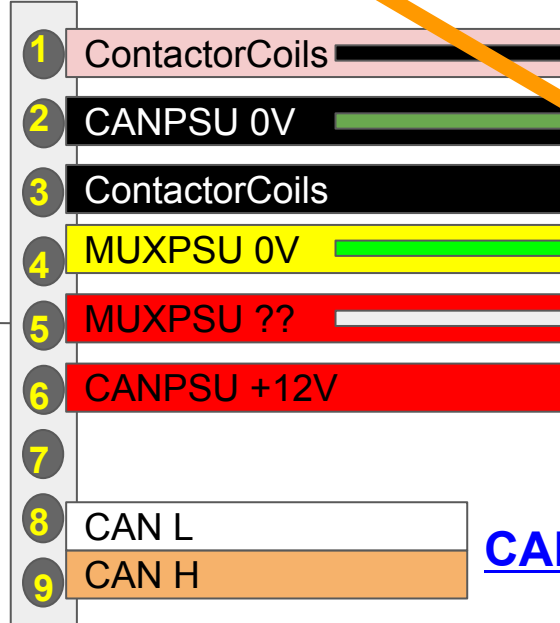

# Rear battery pack

HACK:  
Original defect  
connectors replaced with  
9 pin sub-D  
Female

To front  
battery  
pack's

6 packs moved into  
the car, instead of  
below car

CAN speed\_ 125 Kbps

# LEM 200 Amp current transformer

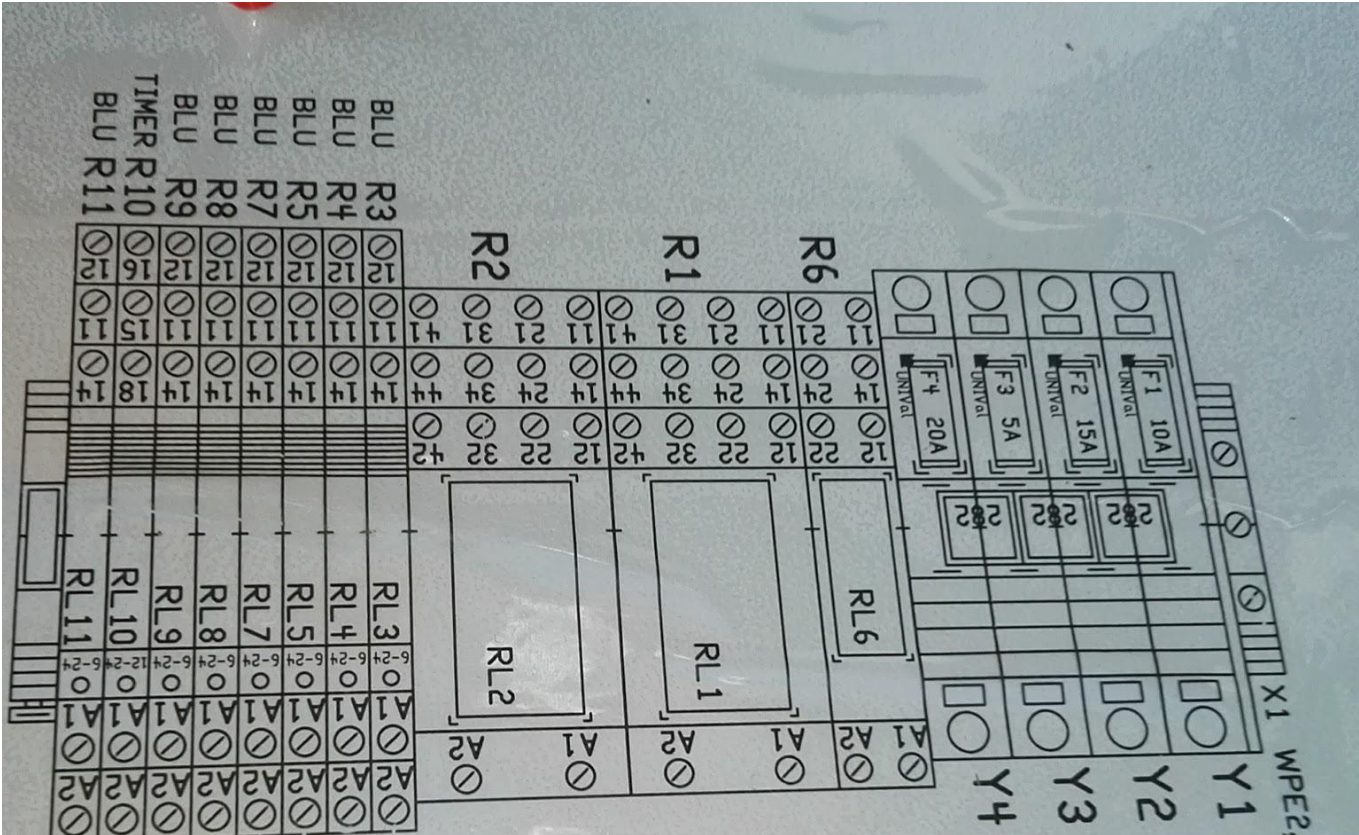

LEM current sensor Supply voltage  
( $\pm 5\%$ ) is  $\pm 15V$  for NCA1C-200A.  
Voltage low is 14,25V for LEM sensor

Placed below right front light,  
and connected

Relay's and fuses in the box in front above battery pack

# BMS MUX main pcb in front (can node or master??)

# BMS pcb top side - mux 24 v2.0

Connectors are molex 43045  
microfit 3

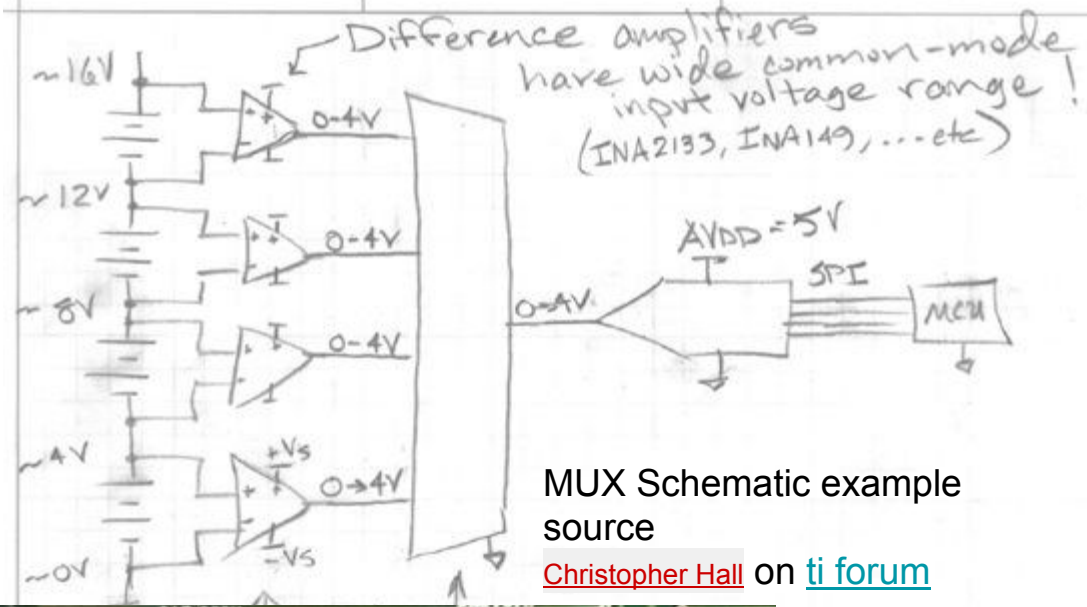

# Battery cell modules

Cells measure/balance module are balanced by a classic transistor driven a load resistor.

Voltages are measured from all cells with multiplexer (called MU or MUX) also by diff amplifiers (LT 1990A)

Opto coupler sends cell status to the microprocessor. Bottom off pcb has optocouplers for balancer control

# BMS pcb bottom side - mux 24 v2.0

# Bms cell input

Diode's protects the cell input

# Components - 12 cells balancing

The balancing transistors/resistors are turned on / off by the microcontroller, through an optocoupler

# BMS PCB connectors

Remember to  
place the  
connectors  
marked with a  
white DOT in  
the correct  
side of the  
pcb!!
